

Appendix A: List of Campaigns Included

Beginning

Year	Campaign	Location
2009	Frente Nacionalæde Resistencia Popular (FNRP)	Honduras
2009	Anti-Socialist Demonstrations	Bulgaria
2009	Moldovan "Grapevine" Revolution	Moldova
2009	2009 Anti-Saakashvili Campaign	Georgia
2009	anti-Rajoelina movement	Madagascar
2009	anti-Ravalomanana movement	Madagascar
2009	Green Revolution and Day of Rage	Iran
2009	Al Qaeda in the Arabian Peninsula	Yemen
2010	Snow Revolution	Russia
2010	Pro-Ouattara Campaign	Ivory Coast
2010	Renewed Western Sahara Independence Protests	Western Sahara
2010	Anti-Abdelaziz Bouteflika Campaign	Algeria
2010	Anti-Ben Ali Campaign (Jasmin Revolution)	Tunisia
2010	Anti-Interim Government	Kyrgyzstan
2010	Second Revolution	Kyrgyzstan
2010	Maoist Anti-Govt Protests	Nepal
2011	Anti-Aziz Protests	Mauritania
2011	Djibouti Arab Spring	Djibouti
2011	Libyan Civil War	Libya
2011	Day of Rage Protests	Iraq
2011	Syrian Uprising	Syria
2011	Syrian Civil War	Syria
2011	Protest for Constitutional Reform	Jordan
2011	Anti Ali Adduallah Saleh Campaign	Yemen
2011	Anti-King Hamad Campaign	Bahrain
2012	2012 Anti-Government Protests	Romania
2012	Northern Mali conflict	Mali
2012	Anti-Wade June 23 Movement	Senegal
2012	Let's Save Togo (Anti-Gnassingbe)	Togo
2012	M23	Democratic Republic of Congo
2012	Anti-Shiite Government Protests	Iraq
2012	Kirti Monastery Protests	China
2012	Anti-Nasheed Campaign	Maldives
2012	Nasheed Supporters	Maldives
2012	Anti-Maoist Campaign	Nepal
2013	Dance with me Campaign	Bulgaria
2013	Euromaidan	Ukraine
2013	anti-Balaka	Central African Republic
2013	Anti-Islamist Government Protests	Tunisia
2013	Protests Against the Crisis Talks	Tunisia
2013	Anti-Erdogan	Turkey

2013	Anti-Morsi Protests	Egypt
2013	Pro-Morsi Protests	Egypt
2013	Sinai Insurgency	Egypt
2013	Islamic State	Syria
2013	Civil Movement for Democracy	Thailand
2013	2013 Cambodian election protests	Cambodia
2014	Anti-Martelly campaign	Haiti
2014	2014 Mexican anti-Corruption Campaign	Mexico
2014	anti-Maduro	Venezuela
2014	UDAR	Bosnia-Herzegovina
2014	Ultras "United Ukraine" Campaign	Ukraine
2014	Rebels in East Ukraine (Ukrainian Civil War)	Ukraine
2014	Anti-Compaore Campaign	Burkina Faso
2014	Islamist militia factions (Second Libyan Civil War)	Libya
2014	Hong Kong pro-democracy (Umbrella Movement)	China
2014	New Democracy Movement	Thailand
2015	Guatemala Uprising	Guatemala
2015	Honduran indignados	Honduras
2015	Out Correa Campaign	Ecuador
2015	Anti-Rousseff	Brazil
2015	Montenegrin Opposition Protest	Montenegro
2015	Colorful Revolution	Macedonia
2015	Kosovo Anti-Government Protests	Kosovo
2015	Moldovan Anti-Government Protest	Moldova
2015	Colectiv Revolution	Romania
2015	Anti-Nkurunziza Campaign	Burundi
2015	Renewed Kurdistan Worker's Party (PKK)	Turkey
2015	Anti-Houthi Movement	Yemen
2015	ISIS-Afghanistan	Afghanistan
2015	Anti-Park protests	South Korea
2015	Western Southeast Asia Front	Myanmar
2015	Anti-Yameen	Maldives
2016	Catalan separatist protest	Spain
2016	Anti-right wing government	Poland
2016	Panama Papers Anti-Government Protest	Iceland
2017	Anti-Morales Protests	Guatemala
2017	Anti-Hernandez	Honduras
2017	Anti-Orban	Hungary
2017	Anti-Vucic	Serbia
2017	Romania anti-government protest	Romania
2017	2017 Anti-Gnassingbe	Togo
2017	anti-Kabila campaign	Democratic Republic of Congo
2017	2017 Iran Anti-Government Protests	Iran
2017	Anti-Erdogan II	Turkey

2018	Anti-Jovenel Moise Protests	Haiti
2018	Anti-Ortega Protests	Nicaragua
2018	Yellow Vests	France
2018	2018 Anti-government protests	Armenia
2019	Hernández Must Go campaign	Honduras
2019	anti-Morales protests	Bolivia
2019	anti-Áñez protests	Bolivia
2019	anti-Pinera	Chile
2019	Albanian anti-corruption	Albania
2019	97000 Resist campaign	Montenegro
2019	2019 Georgian Protests	Georgia
2019	Smile Revolution	Algeria
2019	2019 Iranian protests	Iran
2019	anti-Mahdi movement	Iraq
2019	anti-Sisi protests	Egypt
2019	October Revolution	Lebanon

Appendix B: Object Detection Algorithm Training Discussion

Figure B1 presents the plots of interest for the fine-tuning process of the YOLO v5 for the protest banner detection task. As mentioned in the paper, object detection task requires the model to first, locate the targeted objects, and second, classify the detected objects. Correspondingly, two loss functions are calculated during the model training: box loss (for the location task) and object loss (for the classification task). As shown in the plots, while the box validation loss keeps decreasing, the object validation loss starting increase during the training, which suggests the potential problem of overfitting. Accordingly, for the final algorithm to use, we choose the one with highest [mAP@0.5](#) and [mAP@0.95](#) values instead of the fine-tuned model output at the 100 epochs. And the final evaluation statistics is shown in Table B1 and the evaluation plots are shown in Figure B2.

Figure B1: Training results

Class	Instances	Precision (P)	Recall (R)	mAP@0.5	mAP@0.5:0.95
Protest Sign	781	0.789	0.781	0.813	0.620

Table B1: Best model performance

Figure B2: Evaluation Plots

One of the reasonable concerns shared across the computational social science community is whether the performance of the after-training algorithm is good enough for downstream substantive tasks. Different from many tasks in the computer science field in which most experiments are finished in a laboratory environment with well-designed datasets (or benchmarks), social scientists who want to utilize computational tools often face much messier data. Accordingly, a sophisticated balance is needed for both allowing the social scientists to take advantage of the advanced AI tools as well as ensuring the credibility of the empirical findings from the AI-coded data. In this Appendix, we try to convince the readers that, given the complicated nature of the protest photos online, our choices of computational tools yield enough credibility for the final empirical findings.

Figure B3 provides a straightforward way to visualize the complicated nature lying in the coded dataset. We manually coded 1000 protest photos randomly sampled from the collected database. The left label correlogram plots the information of the ground truth bounding boxes in the coded dataset. The lower right subplot shows that most protest banners annotated are rather small. On the right plot, the subplots on the upper right (all the bounding boxes) and lower left (frequencies of the bounding boxes at each position) suggest that the protest banners could appear in any corners in one photo. The small scale of the banners in photos and the random positions all make the detection task even more challenging. To make it worse, there are many “noisy” photos with low resolution, as shown in Figure A4, in the big dataset, which makes the protest banner detection task in those photos almost impossible.

Figure B3: Distributions of the ground truth bounding boxes

Figure B4: Noisy photos

Despite these challenges, careful training design enabled our algorithm to reach around 0.82 $mAP@0.5$ —state of the art in 2022, when the study was conducted—and performance comparable to other CV-based detectors of the period (Rekavandi et al. 2023) and even to systems used in advanced real-world applications such as autonomous driving (Balasubramaniam & Pasricha 2022). Furthermore, through manual checking on the randomly sampled predictions, the model shows pretty good face validity.

For more rigorous test on the validation of the object detection algorithm, we constructed a small set ($n=50$) of protest photos with complicated features but high resolution. Figure B5 shows some of the sample predictions. And the $mAP@50$ statistic arrives 0.863 with the precision score at 0.902, which is comparable to the performance of more advanced YOLO models that training on much larger datasets.

Figure B5: Face validation of the object detection algorithm on complicated high-resolution protest photos

Appendix C: Statistical Analysis

C.I. Curvilinear Hypothesis Appendix (Hypothesis 1)

Strict-success twins of the H1 main panel, distributional and clustering sensitivity rows, and a forest-plot figure summarizing the curvature coefficient across all 14 H1 specifications.

C.A1. Strict-success and ordered-outcome models

Appendix Table C1: Additional Robustness Models for the Curvilinear Hypothesis: Effect of English-Language Signs on Strict Campaign Success and Ordered Campaign Outcomes, 2009-2019

Weibull accelerated-failure-time (AFT) models for time-to-event outcomes; Firth penalized maximum likelihood for binary success outcomes; adjacent-category ordered logit (Kosmidis-Firth penalty) for ordered campaign outcomes. All annual-campaign Cox proportional-hazards models use counting-process format with standard errors clustered by source campaign.

Columns 1-3 use NAVCO 1.3 campaign-level data: time to strict success, strict-success binary, and ordered campaign success with three categories. Columns 4-6 use NAVCO 2.1 campaign-year panel data: hazard of strict success, yearly strict-success binary, and ordered annual progress with six levels. These specifications complement the main concession-only models by varying the success threshold and outcome scale. Events per variable (EPV) is reported in the table footer; an asterisk marks EPV below 5. EPV is not defined for ordered adjacent-category logit models.

Response	Time to Strict Success	Strict Success (Binary)	Ordered Campaign Success	Hazard of Strict Success	Strict Success Yearly (Binary)	Ordered Annual Progress

C.A2. Distributional and clustering sensitivity

Appendix Table C2: Distributional and Clustering Sensitivity for the Curvilinear Hypothesis: Effect of English-Language Signs on Concession Outcomes Under Alternative Model Specifications, 2009-2019

Sensitivity checks for the inverted-U curvature claim. Column 1 replaces the Weibull baseline with log-normal accelerated-failure-time, addressing concern about distributional leverage of the Weibull functional form. Column 2 drops the parametric baseline assumption entirely with a semi-parametric Cox proportional-hazards model on the NAVCO 1.3 campaign-level sample. Column 3 re-fits the NAVCO 2.1 first-event Cox specification using Andersen-Gill recurrent-event format, retaining repeated within-campaign events instead of truncating after the first concession. Column 4 re-fits the NAVCO 2.1 yearly Firth penalized maximum likelihood model using a generalized estimating equation logit with exchangeable working correlation and source-campaign clustering.

These specifications are robustness checks of individual main-panel models, not additional hypothesis tests, and therefore lie outside the family-wise multiplicity correction applied in the main table. Events per variable (EPV) is reported in the footer; an asterisk marks EPV below 5.

Appendix Figure C1: Forest plot of the squared English-share (curvature) coefficient across all H1 specifications

H1 Curvature Coefficient Across All Specifications

Inverted-U expected sign: + for Weibull AFT / log-normal AFT / brcl; – for Firth PML / Cox PH / GEE logit.

Source: H1_curvilinear_results.csv. CIs use Wald SE on the quadratic term.

Additional response definitions, curvilinear extensions, ordered-outcome models, and robustness specifications for the political vulnerability hypothesis.

Appendix Table C3: Curvilinear Extension of H2.1 — English-Language Signs and Their Squared Term, Conditional on Political Vulnerability to External Pressure, on Campaign Success, 2009-2019

Sign convention: Weibull AFT (cols 1, 2) and Cox PH (cols 5, 6) are time-to-event models — a positive coefficient on the English-share x moderator interaction indicates English is associated with longer (Weibull) or lower-hazard (Cox) time to success (i.e., slows). Firth PML (cols 3, 4 on NAVCO 1.3; cols 7, 8 on NAVCO 2.1) is a binary outcome model — a positive coefficient indicates English is associated with success (i.e., helps). Substantive direction therefore requires reading the model column header.

C.A3. Limited-success H2.1 models

Appendix Table C5: H2.1 Replication on Limited Campaign Success — The Role of English-Language Signs, Conditional on Political Vulnerability to External Pressure, on Limited Success (NAVCO Original Coding), 2009-2019

Weibull AFT Model Used for Time to Limited Success, Penalized Logit Model (PML) Used for Limited Success (Binary), Cox PH Model Used for First Limited-Success Hazard, Standard Errors in Parentheses (standard errors clustered by NAVCO 2.1 source campaign for Cox PH), Profile Confidence Interval for p Value Calculation in PML Models, All Constituent Interaction Terms Mean-Centered, Outcome defined as partial success: campaign-level models use NAVCO 1.3 limited success; annual campaign models use NAVCO 2.1 limited progress

Sign convention: Weibull AFT (cols 1, 2) and Cox PH (cols 5, 6) are time-to-event models — a positive coefficient on the English-share x moderator interaction indicates English is associated with longer (Weibull) or lower-hazard (Cox) time to limited success (i.e., slows). Firth PML (cols 3, 4 on NAVCO 1.3; cols 7, 8 on NAVCO 2.1) is a binary outcome model — a positive coefficient indicates English is associated with limited success (i.e., helps). Substantive direction therefore requires reading the model column header.

C.A4. Additional H2.1 ordered-outcome and robustness models

Appendix Table C6: Additional H2.1 Ordered-Outcome and Robustness Models — The Role of English-Language Signs, Conditional on Political Vulnerability to External Pressure, on Campaign Progress and Concession, 2009-2019

Adjacent-category ordered logit models are used for ordered campaign success and ordered annual progress. Recurrent-event Cox models are used for repeated concession hazards, and clustered GEE logit models are used for yearly concession outcomes. Standard errors for annual campaign models are clustered by NAVCO 2.1 source campaign; all interaction terms use mean-centered constituent variables.

Columns 1-4 report ordered-outcome extensions for campaign-level success and annual campaign progress. Columns 5-8 report annual campaign robustness checks using recurrent-event Cox models and clustered GEE logit models. These models are additional appendix diagnostics rather than the confirmatory main-table specifications. EPV means events per variable; an asterisk marks EPV below 5. EPV is not defined for ordered adjacent-category logit models.

Weibull AFT Model Used for Time to Success, Penalized Logit Model (PML) Used for Success (Binary), Standard Errors in Parentheses, Profile Confidence Interval for p Value Calculation in PML Models, All Constituent Interaction Terms Mean-Centered.

Success/concession is broad NAVCO success in NAVCO 1.3: full success or limited concession. This table reproduces the Table 3 response family for appendix comparability.

Sign convention: Weibull AFT columns are time-to-event models, so a positive coefficient on the English-share x moderator interaction indicates English is associated with longer time to success. Firth PML columns are binary-outcome models, so a positive coefficient indicates English is associated with greater probability of success.

Weibull AFT Model Used for Time to Success, Penalized Logit Model (PML) Used for Success (Binary), Standard Errors in Parentheses, Profile Confidence Interval for p Value Calculation in PML Models, All Constituent Interaction Terms Mean-Centered.

Success is strict full success in NAVCO 1.3; limited/concession outcomes are coded as non-success in this appendix table.

Sign convention: Weibull AFT columns are time-to-event models, so a positive coefficient on the English-share x moderator interaction indicates English is associated with longer time to success. Firth PML columns are binary-outcome models, so a positive coefficient indicates English is associated with greater probability of success.

Cox PH Model Used for Hazard of First Success, Penalized Logit Model (PML) Used for Yearly Success (Binary), Standard Errors in Parentheses, NAVCO 2.1 Source-Campaign-Clustered Robust Standard Errors for Cox PH, Profile Confidence Interval for p Value Calculation in PML Models, All Constituent Interaction Terms Mean-Centered.

Success is strict complete success in NAVCO 2.1 (progress = 4); concession years are coded as non-success in this appendix table.

Sign convention: Cox PH columns are hazard models, so a positive coefficient indicates a higher hazard of first success. Firth PML columns are yearly binary-outcome models, so a positive coefficient indicates greater yearly probability of success.

Recurrent-event Cox proportional-hazards models and campaign-clustered GEE logit models are used for annual broad-success/concession robustness checks. Standard errors are reported in parentheses, and all interaction terms use mean-centered constituent variables.

These robustness rows are outside the confirmatory Table 3 multiplicity family and should be read as appendix diagnostics.

*** p<0.01, ** p<0.05, * p<0.1

Part IV. Domestic / Internal Vulnerability Models (Hypothesis 3)

Strict-success twins of the H3 main panel, ordered-outcome models on both NAVCO 1.3 and NAVCO 2.1 data, campaign-year concession and strict-success models, recurrent-event Cox and source-clustered GEE sensitivity rows, and additional V-Dem domestic-openness moderators. A forest-plot figure summarizes the interaction coefficient across all 48 H3 specifications.

C.A1. Strict-success campaign-level models

Appendix Table C15: Strict-Success Campaign-Level Models for the Domestic Vulnerability Hypothesis: Effect of English-Language Signs Conditional on Domestic Institutional Openness, 2009-2019

Weibull accelerated-failure-time models (columns 1-4) and Firth penalized maximum likelihood models (columns 5-8) on NAVCO 1.3 campaign-level data. These are strict-success twins of the main concession-only specifications. When CSO Repression serves as the moderator (columns 1 and 5), the domestic control swaps from CSO Repression to Polity Score to avoid moderator-control collinearity; all other columns use CSO Repression as the domestic control. All interaction terms use mean-centered constituent variables.

These rows complement the main table and are adjusted with the Benjamini-Hochberg correction within the appendix-grade family. Events per variable (EPV) is reported in the footer; an asterisk marks EPV below 5.

C.A2. Ordered-outcome models on campaign success and annual progress

Appendix Table C16: Ordered-Outcome Models for the Domestic Vulnerability Hypothesis: Adjacent-Category Logit on Campaign Success and Annual Progress, Conditional on Domestic Institutional Openness, 2009-2019

Adjacent-category ordered logit with parallel slopes (Kosmidis-Firth penalty) on two outcomes: campaign-level three-category success on NAVCO 1.3 (columns 1-4) and annual progress on a six-level scale with failure coded separately from status quo on NAVCO 2.1 (columns 5-8). Both panels test the same four moderators of domestic institutional openness. When CSO Repression serves as the moderator, the domestic control swaps to Polity Score on NAVCO 1.3 and to none on NAVCO 2.1, avoiding moderator-control collinearity. Category-specific intercepts are omitted from the table; reported coefficients are the shared parallel-slope predictor effects.

All rows are adjusted with the Benjamini-Hochberg correction within the appendix-grade family. Events per variable is not defined for ordered adjacent-category logit models.

Response	Success (3-cat, NAVCO 1.3)	Success (3-cat, NAVCO 1.3)	Success (3-cat, NAVCO 1.3)	Success (3-cat, NAVCO 1.3)	Progress (6- level, NAVCO 2.1)	Progress (6- level, NAVCO 2.1)	Progress (6- level, NAVCO 2.1)	Progress (6- level, NAVCO 2.1)

C.A3. Campaign-year concession models

Appendix Table C17: Campaign-Year Concession Models for the Domestic Vulnerability Hypothesis: Cox Proportional-Hazards and Firth Logit on NAVCO 2.1 Panel, Conditional on Domestic Institutional Openness, 2009-2013

Cox proportional-hazards models on first-event concession hazard (columns 1-4, counting-process format) and Firth penalized maximum likelihood on yearly concession-binary outcomes (columns 5-8). Standard errors are clustered by source campaign. When CSO Repression serves as the moderator (columns 1 and 5), the domestic control is omitted (no Polity swap) to avoid moderator-control collinearity.

All rows are adjusted with the Benjamini-Hochberg correction within the appendix-grade family. Events per variable (EPV) is reported in the footer; an asterisk marks EPV below 5.

C.A4. Campaign-year strict-success models

Appendix Table C18: Campaign-Year Strict-Success Models for the Domestic Vulnerability Hypothesis: Cox Proportional-Hazards and Firth Logit on NAVCO 2.1 Panel, Conditional on Domestic Institutional Openness, 2009-2013

Strict-success twins of the campaign-year panel: Cox proportional-hazards on hazard of full success (columns 1-4, counting-process format) and Firth penalized maximum likelihood on yearly strict-success binary (columns 5-8). Standard errors are clustered by source campaign. When CSO Repression serves as the moderator, the domestic control is omitted to avoid moderator-control collinearity.

All rows are adjusted with the Benjamini-Hochberg correction within the appendix-grade family. Events per variable (EPV) is reported in the footer; an asterisk marks EPV below 5.

C.A5. Recurrent-event and clustering sensitivity

Appendix Table C19: Recurrent-Event and Clustering Sensitivity for the Domestic Vulnerability Hypothesis: Andersen-Gill Recurrent-Event Cox and Source-Clustered GEE Logit Companion Models on NAVCO 2.1 Panel, 2009-2013

Sensitivity checks for the campaign-year results. Columns 1-4 re-fit the Cox proportional-hazards concession models using Andersen-Gill recurrent-event format on the full panel (no first-event truncation). Columns 5-8 re-fit the yearly Firth concession models using generalized estimating equation logit with exchangeable working correlation and source-campaign clustering.

These specifications are robustness checks of individual main-panel models, not additional hypothesis tests, and therefore lie outside the family-wise multiplicity correction. Events per variable (EPV) is reported in the footer; an asterisk marks EPV below 5.

C.A6. Additional V-Dem domestic-openness moderators

Appendix Table C20: Additional Domestic-Openness Moderators for the Domestic Vulnerability Hypothesis: Political Civil Liberties and Freedom of Association Companion Models, 2009-2019

Standalone extension to the main domestic-vulnerability table, testing two additional V-Dem moderators of domestic institutional openness: Political Civil Liberties (columns 1-2, included in the main panel as a parity check) and Freedom of Association thick index (columns 3-4, new). Columns 1 and 3 use Weibull accelerated-failure-time on time to broad concession; columns 2 and 4 use Firth penalized maximum likelihood on the binary broad-concession outcome. All interaction terms use mean-centered constituent variables.

These models extend the moderator set beyond the four moderators in the main panel (CSO Repression, Civil Liberties, Political Liberty, Polity Score). Controls are suppressed from the table for compactness. Events per variable (EPV) is reported in the footer; an asterisk marks EPV below 5.

Part VI. Power Diagnostics

Power diagnostics for the main-paper models, with Cox power simulations that fail calibration checks excluded from reader-facing summaries.

POWER. Main-model power diagnostics

Appendix Table C25: Power Diagnostics for Main-Paper Models

Reported power is the simulated rejection rate when the true focal effect is set equal to the fitted coefficient from the corresponding reported model. All values are drawn directly from the power diagnostic outputs.

H1 appears twice per reported model because the diagnostics report both the published squared-English coefficient test and the joint English-share test. Cox power rows that fail calibration checks are excluded from this reader-facing table. Weibull rows for the economic vulnerability and domestic-institution models are treated as diagnostics because the nominal Wald tests are not size-calibrated.

Power analysis method.

The reported power values are estimated by Monte Carlo simulation, not by closed-form analytic power formulas. Each power script uses the observed covariate distribution and the corresponding fitted model as the design template. For each model, the focal coefficient is set to a grid of effect-size multipliers (0, 0.25, 0.5, 1.0, and 2.0 times the fitted coefficient), simulated outcomes are generated, the original model is refit, and the focal p-value is recorded. Power is the share of simulated replications in which the focal test rejects at alpha = 0.05 (Baranger et al. 2023).

The outcome simulator follows the estimator. Firth penalized logit rows simulate binary outcomes from Bernoulli draws using the fitted logit probability. Weibull accelerated-failure-time rows simulate event times from the fitted Weibull model and censor simulated event times at the observed campaign duration. Cox proportional-hazards power rows are excluded from this reader-facing table because the calibration audit found invalid or inflated false-positive rates under the current risk-set simulator.

The false-positive-rate column reports the Monte Carlo rejection rate when the true focal effect is set to zero. The fitted-effect-power column reports the rejection rate when the true focal effect equals the fitted coefficient. Minimum-detectable-effect diagnostics, where reported in the source files, are derived from the same simulation grid rather than from an analytic formula. The separate Weibull bootstrap calibration diagnoses small-sample false-positive behavior of the Weibull Wald tests; it is used to flag nominal-Wald rows, not to replace the Monte Carlo power estimates reported here.

Column notation.

Family identifies the hypothesis family; main table identifies the corresponding table in the manuscript; main-table model label gives the label used in that table; estimator records the fitted model class; and focal test identifies the coefficient or joint test for which power is reported.

Power at fitted effect is the simulated rejection rate at the nominal 0.05 level when the true focal effect equals the fitted coefficient from the reported model. False-positive rate is the simulated rejection rate at the nominal 0.05 level when the true focal effect is set to zero.

Status / note flags rows that should be treated as diagnostics rather than size-calibrated power estimates, including nominal-Wald Weibull diagnostics.

Implications for power analysis.

Because the analysis is constrained to a substantively bounded set of campaigns, we do not treat the conventional 0.80 benchmark as a sharp pass/fail threshold. Instead, the table reports per-test Monte Carlo power as a graded design-sensitivity diagnostic: the question is how much information the observed design contains about the fitted focal effect, not whether the design crosses a universal adequacy line (Bacchetti 2010; Lakens 2022).

On that graded reading, H1 remains weak after Cox diagnostics that fail calibration checks are excluded: the valid Weibull and Firth rows have low to modest fitted-effect power. The excluded Cox rows are retained only in the inference-diagnostics appendix because the audit flags the simulated risk-set process as invalid for reader-facing power analysis.

H2.1 is the weakest family among the main interaction tests. After excluding Cox rows that fail calibration checks, the Table 2 power evidence comes from the Weibull and Firth specifications, including the NAVCO 2.1 yearly Firth rows. Weak or unstable H2.1 findings should therefore be interpreted as both substantively weak and statistically underpowered; the diagnostics cannot rule out meaningful false negatives for that hypothesis. This is consistent with broader evidence that interaction-heavy quantitative political science designs often have limited power in small samples (Arel-Bundock et al. 2026; Baranger et al. 2023).

For H2.2 and H3, the picture is more informative but still not uniformly high-powered. Some valid Firth PML interaction models show moderate raw fitted-effect power, especially H2.2 trade openness (0.673), H2.2 IO donor count (0.695), and H3 polity (0.677), while the H3 repression, civil-liberties, and political-liberty Firth models fall around 0.46 to 0.48. Other focal tests remain weak, including H2.2 FDI inflows (0.049) and H2.2 foreign aid (0.217). The Weibull rows for H2.2 and H3 should be read only as nominal-Wald diagnostics rather than size-calibrated power estimates.

The resulting interpretation is mixed but not empty. The design retains nontrivial ability to detect the larger fitted interaction patterns in several H2.2 and H3 Firth specifications, while H1 and especially H2.1 remain fragile. The appendix table should therefore be read as a transparency check that distinguishes very weak hypothesis families from more informative, but still small-N-constrained, interaction tests.

Part VII. Inference Diagnostics

Cox proportional-hazards diagnostics, Cox power-simulation calibration checks, and Weibull bootstrap calibration diagnostics.

INF. Survival and power inference diagnostics

Appendix Table C26: Inference Diagnostics for Survival and Power Analyses

This table consolidates inference diagnostics generated by the analysis workflow. It separates Cox proportional-hazards assumption checks, Cox power rows excluded from reader-facing power summaries, and Weibull bootstrap calibration diagnostics. These rows are diagnostics and provenance checks; they do not replace the main coefficient tables.

Panel A. Cox proportional-hazards diagnostics

Proportional-hazards diagnostics are reported for first-event Cox rows where available. Recurrent-event robustness rows are explicitly marked when the diagnostic is not available from the inference-diagnostics output.

Panel B. Cox power quarantine diagnostics

These rows were excluded from reader-facing power summaries because the current Cox power simulator does not preserve the fitted risk-set structure.

Family	Model	Estimator	Moderator	Rows removed	False-positive rate at zero effect	Power at fitted effect	Calibration status	Quarantine reason	Reporting status	Source
H1	H1; Cox PH (counting-process); Moderator: (none — H1 unconditional curvilinear)	Cox PH (counting-process)	(none — H1 unconditional curvilinear)	2	0.222	0.992	Degenerate fitted model	Risk-set simulation not valid	Excluded after calibration check	power_h1_summary.csv
